

Working on this project was a hands-on experience in object oriented programming as well as inheritance. Creating the Assignment class as a parent class aided in reducing repetition within the homework and exam classes. I learned how functions operate within and outside a class as well as how a dictionary of functions can operate without accessing their memory locations directly.

One challenge however, was creating functions while still maintaining the user facing program. Initially, I wanted my functions to use parameters because I understood parameters as a way of making functions more flexible and reusable. However this created a problem, the user was now required to know all the parameters for all functions. In the event that the user failed to provide these parameters, the program would terminate. So I compromised, I made my functions without parameters, within these functions, I asked the user to input().

I also faced challenges in validating user inputs. I had to effectively use multiple try- except blocks. This ensured that the program runs smoothly. Other errors include dates being stored as strings rather than date time objects, this was due to the fact that I failed to reassign the string as a datetime object. Division by zero error, made from the grade summary function, this occurred when there was no homework or exam. I also grappled with understanding git and managing different versions of my project.

With more time, I would add a way to edit or delete an assignment. I would also consider allowing my integer inputs to take their string equivalent. For example twelve == 12. I would also make the interface more user friendly. This assignment has been about programming, debugging, viewing the program from a user point of view and functional design.
